Computer Abstractions and Technology

[Adapted from Computer Organization and Design, Patterson & Hennessy, courtesy for Mary Jane Irwin]

The Computer Revolution

- Progress in computer technology
 - Underpinned by Moore's Law
- Makes novel applications feasible
 - Computers in automobiles
 - Cell phones
 - Human genome project
 - World Wide Web
 - Search Engines
- Computers are pervasive

Classes of Computers

- Personal computers
 - General purpose, variety of software
 - Subject to cost/performance tradeoff
- Server computers
 - Network based
 - High capacity, performance, reliability
 - Range from small servers to building sized

Classes of Computers

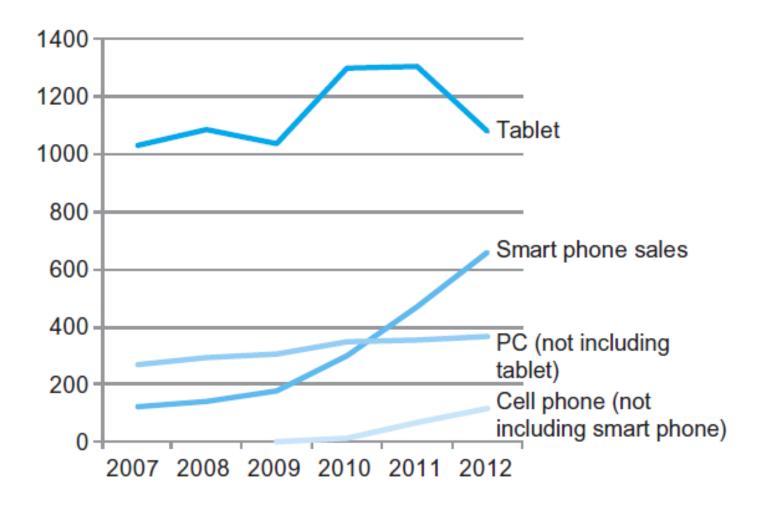

Supercomputers

- High-end scientific and engineering calculations
- Highest capability but represent a small fraction of the overall computer market

Embedded computers

- Hidden as components of systems
- Stringent power/performance/cost constraints

The PostPC Era

The PostPC Era

- Personal Mobile Device (PMD)
 - Battery operated
 - Connects to the Internet
 - Hundreds of dollars
 - Smart phones, tablets, electronic glasses
- Cloud computing
 - Warehouse Scale Computers (WSC)
 - Software as a Service (SaaS)
 - Portion of software run on a PMD and a portion run in the Cloud
 - Amazon and Google

What You Will Learn

- How programs are translated into the machine language
 - And how the hardware executes them
- The hardware/software interface
- What determines program performance
 - And how it can be improved
- How hardware designers improve performance
- What is parallel processing

Understanding Performance

- Algorithm
 - Determines number of operations executed
- Programming language, compiler, architecture
 - Determine number of machine instructions executed per operation
- Processor and memory system
 - Determine how fast instructions are executed
- □ I/O system (including OS)
 - Determines how fast I/O operations are executed

Eight Great Ideas

- Design for Moore's Law
- Use abstraction to simplify design
- Make the common case fast
- Performance via parallelism
- Performance via pipelining
- Performance via prediction
- Hierarchy of memories
- Dependability via redundancy

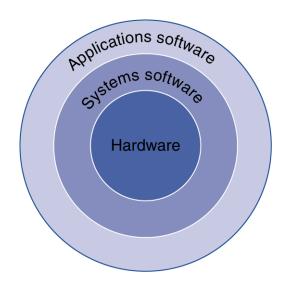

Below Your Program

- Application software
 - Written in high-level language
- System software
 - Compiler: translates HLL code to machine code
 - Operating System: service code
 - Handling input/output
 - Managing memory and storage
 - Scheduling tasks & sharing resources
- Hardware
 - □ Processor, memory, I/O controllers

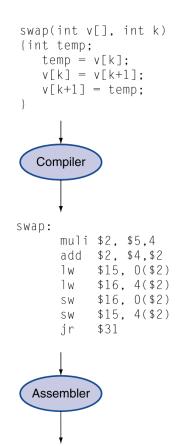

Levels of Program Code

- □ High-level language
 - Level of abstraction closer to problem domain
 - Provides for productivity and portability
- Assembly language
 - Textual representation of instructions
- Hardware representation
 - Binary digits (bits)
 - Encoded instructions and data

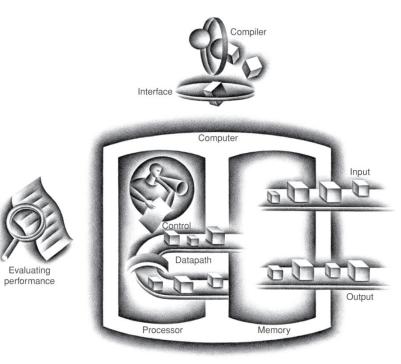

High-level language program (in C)

Assembly language program (for MIPS)

Binary machine language program (for MIPS)

Components of a Computer

- Same components for all kinds of computer
 - Desktop, server, embedded
- Input/output includes
 - User-interface devices
 - Display, keyboard, mouse
 - Storage devices
 - Hard disk, CD/DVD, flash
 - Network adapters
 - For communicating with other computers

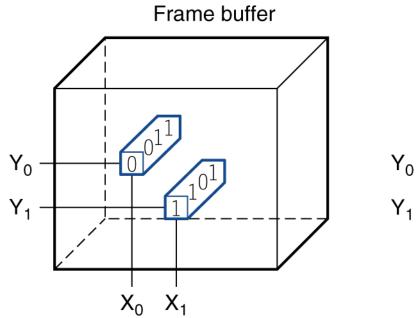

Touchscreen

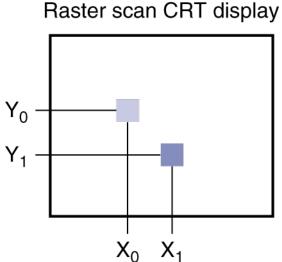

- PostPC device
- Supersedes keyboard and mouse
- Resistive and Capacitive types
 - Most tablets, smart phones use capacitive
 - Capacitive allows multiple touches simultaneously

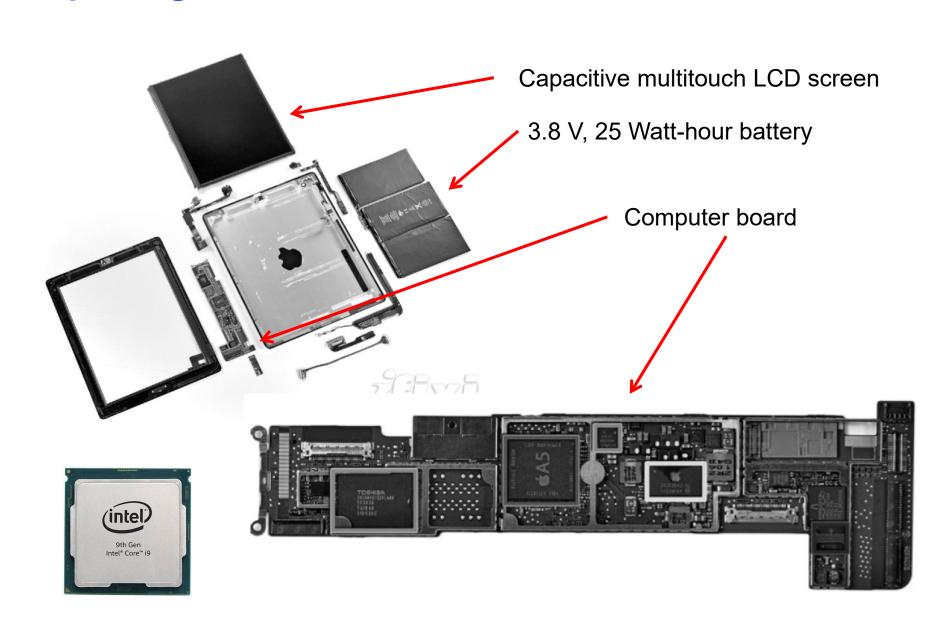

Through the Looking Glass

- □ LCD screen: picture elements (pixels)
 - Mirrors content of frame buffer memory

Opening the Box

Inside the Processor (CPU)

- Datapath: performs operations on data
- Control: sequences datapath, memory, ...
- Cache memory
 - Small fast SRAM memory for immediate access to data

Inside the Processor

Apple A5

Abstractions

- Abstraction helps us deal with complexity
 - Hide lower-level detail
- Instruction set architecture (ISA)
 - The hardware/software interface
- Application binary interface
 - The ISA plus system software interface
- Implementation
 - The details underlying and interface

A Safe Place for Data

- Volatile main memory
 - Loses instructions and data when power off
- Non-volatile secondary memory
 - Magnetic disk
 - Flash memory
 - Optical disk (CDROM, DVD)

Networks

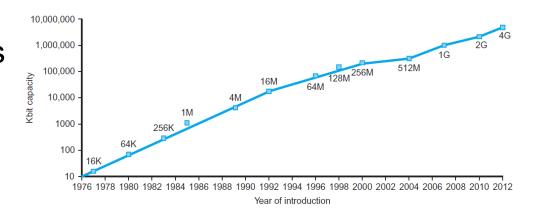

- Communication, resource sharing, nonlocal access
- □ Local area network (LAN): Ethernet
- Wide area network (WAN): the Internet
- Wireless network: WiFi, Bluetooth

Technology Trends

- Electronics technology continues to evolve
 - Increased capacity and performance
 - Reduced cost

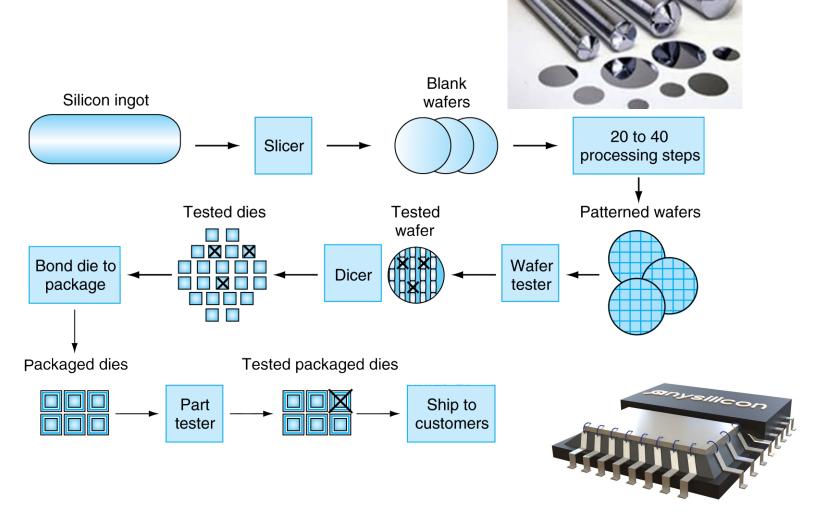

DRAM capacity

Year	Technology	Relative performance/cost	
1951	Vacuum tube	1	
1965	Transistor	35	
1975	Integrated circuit (IC)	900	
1995	Very large scale IC (VLSI)	2,400,000	
2013	Ultra large scale IC	250,000,000,000	

Semiconductor Technology

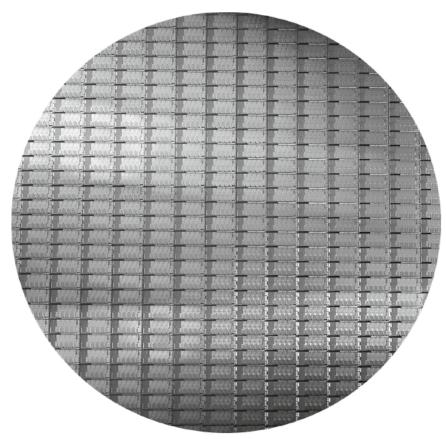

- □ Silicon: semiconductor
- Add materials to transform properties:
 - Conductors
 - Insulators
 - Switch

Manufacturing ICs

□ Yield: proportion of working dies per wafer

Intel Core i7 Wafer

- □ 300mm wafer, 280 chips, 32nm technology
- □ Each chip is 20.7 x 10.5 mm

Integrated Circuit Cost

Cost per die =
$$\frac{\text{Cost per wafer}}{\text{Dies per wafer} \times \text{Yield}}$$

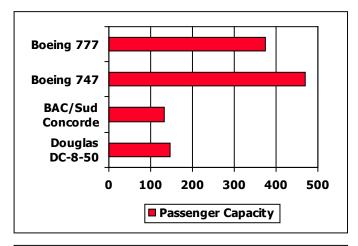

Dies per wafer ≈ Wafer area/Die area

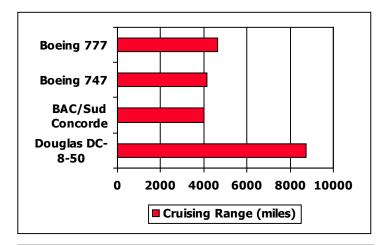

Yield =
$$\frac{1}{(1+(\text{Defects per area}\times\text{Die area/2}))^2}$$

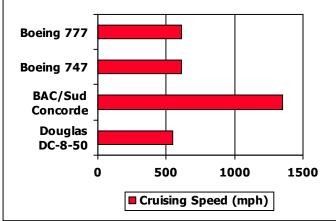

- Nonlinear relation to area and defect rate
 - Wafer cost and area are fixed
 - Defect rate determined by manufacturing process
 - Die area determined by architecture and circuit design

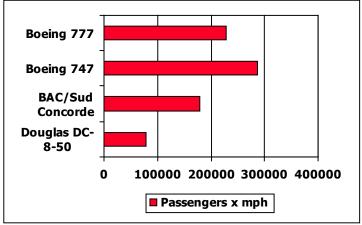

Defining Performance

■ Which airplane has the best performance?

Response Time and Throughput

- Response time
 - How long it takes to do a task
- Throughput
 - Total work done per unit time
 - e.g., tasks/transactions/... per hour
- How are response time and throughput affected by
 - Replacing the processor with a faster version?
 - Adding more processors?
- We'll focus on response time for now...

Relative Performance

- Define Performance = 1/Execution Time
- □ "X is *n* time faster than Y"
 - Performance_x/Performance_y
 - = Execution time $_{Y}$ /Execution time $_{X} = n$
- Example: time taken to run a program
 - 10s on A, 15s on B
 - Execution Time_B / Execution Time_A= 15s / 10s = 1.5
 - So A is 1.5 times faster than B

Measuring Execution Time

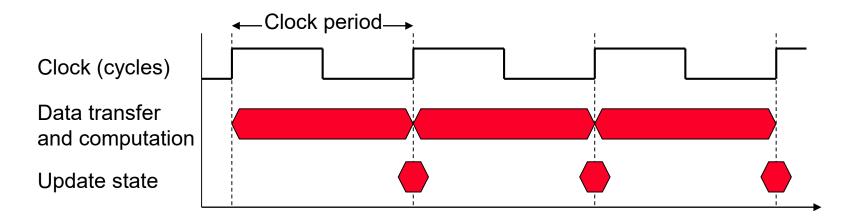

- Elapsed time
 - □ Total response time, including all aspects
 - Processing, I/O, OS overhead, idle time
 - Determines system performance

CPU time

- Time spent processing a given job
 - Discounts I/O time, other jobs' shares
- Comprises user CPU time and system CPU time
- Different programs are affected differently by CPU and system performance

CPU Clocking

Operation of digital hardware governed by a constant-rate clock

- Clock period: duration of a clock cycle
 - \Box e.g., 250ps = 0.25ns = 250 × 10⁻¹²s
- Clock frequency (rate): cycles per second
 - e.g., 4.0GHz = 4000MHz = 4.0×10^9 Hz

CPU Time

- Performance improved by
 - Reducing number of clock cycles
 - Increasing clock rate
 - Hardware designer must often trade off clock rate against cycle count

CPU Time Example

- Computer A: 2GHz clock, 10s CPU time
- Designing Computer B
 - Aim for 6s CPU time
 - □ Can do faster clock, but causes 1.2 × clock cycles
- How fast must Computer B clock be?

$$Clock Rate_{B} = \frac{Clock Cycles_{B}}{CPU Time_{B}} = \frac{1.2 \times Clock Cycles_{A}}{6s}$$

$$Clock\ Cycles_A = CPU\ Time_A \times Clock\ Rate_A$$

$$= 10s \times 2GHz = 20 \times 10^9$$

Clock Rate_B =
$$\frac{1.2 \times 20 \times 10^9}{6s} = \frac{24 \times 10^9}{6s} = 4$$
GHz

Instruction Count and CPI

Clock Cycles = Instruction Count × Cycles per Instruction

CPU Time = Instruction Count × CPI × Clock Cycle Time

- Instruction Count for a program
 - Determined by program, ISA and compiler
- Average cycles per instruction
 - Determined by CPU hardware
 - If different instructions have different CPI
 - Average CPI affected by instruction mix

CPI Example

- □ Computer A: Cycle Time = 250ps, CPI = 2.0
- □ Computer B: Cycle Time = 500ps, CPI = 1.2
- Same ISA
- Which is faster, and by how much?

$$CPUTime_{A} = Instruction Count \times CPI_{A} \times Cycle Time_{A}$$

$$= I \times 2.0 \times 250 ps = I \times 500 ps$$

$$A \text{ is faster...}$$

$$\begin{aligned} \text{CPU Time}_B &= \text{Instruction Count} \times \text{CPI}_B \times \text{Cycle Time}_B \\ &= \text{I} \times 1.2 \times 500 \text{ps} = \text{I} \times 600 \text{ps} \end{aligned}$$

$$\frac{\text{CPU Time}_{B}}{\text{CPU Time}_{A}} = \frac{I \times 600 \text{ps}}{I \times 500 \text{ps}} = 1.2$$

...by this much

CPI in More Detail

If different instruction classes take different numbers of cycles

Clock Cycles =
$$\sum_{i=1}^{n} (CPI_i \times Instruction Count_i)$$

Weighted average CPI

$$CPI = \frac{Clock \ Cycles}{Instruction \ Count} = \sum_{i=1}^{n} \left(CPI_i \times \frac{Instruction \ Count_i}{Instruction \ Count} \right)$$

Relative frequency

CPI Example

Alternative compiled code sequences using instructions in classes A, B, C

Class	А	В	С
CPI for class	1	2	3
IC in sequence 1	2	1	2
IC in sequence 2	4	1	1

- □ Sequence 1: IC = 5
 - □ Clock Cycles = 2×1 + 1×2 + 2×3 = 10
 - □ Avg. CPI = 10/5 = 2.0

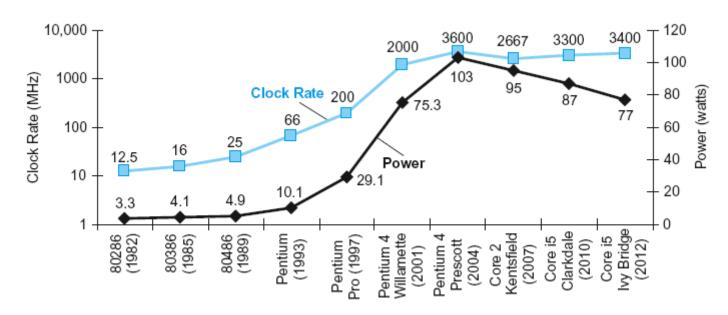

- □ Sequence 2: IC = 6
 - □ Cycles = $4 \times 1 + 1 \times 2 + 1 \times 3$ = 9
 - □ Avg. CPI = 9/6 = 1.5

Performance Summary

$$CPU Time = \frac{Instructions}{Program} \times \frac{Clock \ cycles}{Instruction} \times \frac{Seconds}{Clock \ cycle}$$

- Performance depends on
 - Algorithm: affects IC, possibly CPI
 - Programming language: affects IC, CPI
 - Compiler: affects IC, CPI
 - Instruction set architecture: affects IC, CPI, T_c

Power Trends

In CMOS IC technology

Power = Capacitive load× Voltage² × Frequency

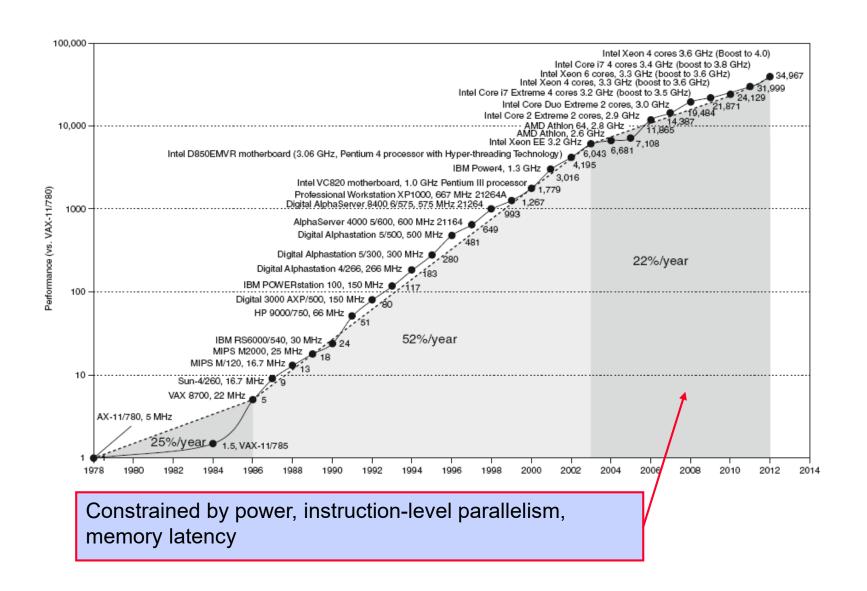

Reducing Power

- Suppose a new CPU has
 - 85% of capacitive load of old CPU
 - 15% voltage and 15% frequency reduction

$$\frac{P_{\text{new}}}{P_{\text{old}}} = \frac{C_{\text{old}} \times 0.85 \times (V_{\text{old}} \times 0.85)^2 \times F_{\text{old}} \times 0.85}{C_{\text{old}} \times V_{\text{old}}^2 \times F_{\text{old}}} = 0.85^4 = 0.52$$

- The power wall
- □ How else can we improve performance?
 - We can't reduce voltage further
 - We can't remove more heat

Uniprocessor Performance

Multiprocessors

- Multicore microprocessors
 - More than one processor per chip
- Requires explicitly parallel programming
 - Compare with instruction level parallelism
 - Hardware executes multiple instructions at once
 - Hidden from the programmer
 - Hard to do
 - Programming for performance
 - Load balancing
 - Optimizing communication and synchronization

SPEC CPU Benchmark

- Programs used to measure performance
 - Supposedly typical of actual workload
- Standard Performance Evaluation Corp (SPEC)
 - Develops benchmarks for CPU, I/O, Web, ...
- SPEC CPU2006
 - Elapsed time to execute a selection of programs
 - Negligible I/O, so focuses on CPU performance
 - Normalize relative to reference machine
 - Summarize as geometric mean of performance ratios
 - CINT2006 (integer) and CFP2006 (floating-point)

$$\int_{1}^{n} \prod_{i=1}^{n} Execution time ratio_{i}$$

CINT2006 for Intel Core i7 920

Description	Name	Instruction Count x 10 ⁹	CPI	Clock cycle time (seconds x 10 ⁻⁹)	Execution Time (seconds)	Reference Time (seconds)	SPECratio
Interpreted string processing	perl	2252	0.60	0.376	508	9770	19.2

SPEC Power Benchmark

- Power consumption of server at different workload levels
 - Performance: ssj_ops/sec
 - Power: Watts (Joules/sec)

Overall ssj_ops per Watt =
$$\left(\sum_{i=0}^{10} ssj_ops_i\right) / \left(\sum_{i=0}^{10} power_i\right)$$

SPECpower_ssj2008 for Xeon X5650

Target Load %	Performance (ssj_ops)	Average Power (Watts)	
100%	865,618	258	
90%	786,688	242	
80%	698,051	224	
70%	607,826	204	
60%	521,391	185	
50%	436,757	170	
40%	345,919	157	
30%	262,071	146	
20%	176,061	135	
10%	86,784	121	
0%	0	80	
Overall Sum	4,787,166	1,922	
Σ ssj_ops/ Σ power =		2,490	

Pitfall: Amdahl's Law

Improving an aspect of a computer and expecting a proportional improvement in overall performance

$$T_{improved} = \frac{T_{affected}}{improvement factor} + T_{unaffected}$$

- □ Example: multiply accounts for 80s/100s
 - How much improvement in multiply performance to get 5× overall?
 - Can't be done! $20 = \frac{80}{n} + 20$
- Corollary: make the common case fast

Fallacy: Low Power at Idle

- Look back at i7 power benchmark
 - At 100% load: 258W
 - At 50% load: 170W (66%)
 - At 10% load: 121W (47%)
- Google data center
 - Mostly operates at 10% 50% load
 - At 100% load less than 1% of the time
- Consider designing processors to make power proportional to load

Pitfall: MIPS as a Performance Metric

- MIPS: Millions of Instructions Per Second
 - Doesn't account for
 - Differences in ISAs between computers
 - Differences in complexity between instructions

$$\begin{aligned} \text{MIPS} &= \frac{Instruction \, count}{Execution \, time \times 10^6} \\ &= \frac{Instruction \, count}{Instruction \, count \times CPI} \times 10^6 \\ &= \frac{Clock \, rate}{CPI \times 10^6} \end{aligned}$$

CPI varies between programs on a given CPU

Concluding Remarks

- Cost/performance is improving
 - Due to underlying technology development
- Hierarchical layers of abstraction
 - In both hardware and software
- Instruction set architecture
 - The hardware/software interface
- Execution time: the best performance measure
- Power is a limiting factor
 - Use parallelism to improve performance
